# Market mechanism

## Market rules

There is **one type of stock**

Each agent can own at most **one share**

# Market mechanism

## Market rules

There is **one type of stock**

Each agent can own at most **one share**

## Types of agents

$N$  **noise traders** :

- $N/2$  potential **sellers**
- $N/2$  potential **buyers**

# Market mechanism

## Market rules

There is **one type of stock**

Each agent can own at most **one share**

## Types of agents

$N$  **noise traders** :

- $N/2$  potential **sellers**
- $N/2$  potential **buyers**

## Prices

$$Prices \in \llbracket 0, P_{max} \rrbracket$$

## Market initialization

$$P_b^0 \hookrightarrow U_{\llbracket 0, \frac{P_{max}}{2} \rrbracket}$$
$$P_s^0 \hookrightarrow U_{\llbracket \frac{P_{max}}{2}, P_{max} \rrbracket}$$

## Market initialization

$$P_b^0 \hookrightarrow U_{\llbracket 0, \frac{P_{max}}{2} \rrbracket}$$
$$P_s^0 \hookrightarrow U_{\llbracket \frac{P_{max}}{2}, P_{max} \rrbracket}$$

## Price evolution

At each time step  $t$ , with **equal probability** :

$$P_b^{t+1} = P_b^t \pm 1$$
$$P_s^{t+1} = P_s^t \pm 1$$

# Simulation process

- 1 Initialize a market with  $N$  agents,  $T$  time steps

# Simulation process

- ① Initialize a market with  $N$  agents,  $T$  time steps
- ② At each time step  $t$  :
  - All prices are **updated**

# Simulation process

- ① Initialize a market with  $N$  agents,  $T$  time steps
- ② At each time step  $t$  :
  - All prices are **updated**
  - **One agent** is chosen **randomly** (buyer or seller). Let's suppose it is a buyer

# Simulation process

- ① Initialize a market with  $N$  agents,  $T$  time steps
- ② At each time step  $t$  :
  - All prices are **updated**
  - **One agent** is chosen **randomly** (buyer or seller). Let's suppose it is a buyer
  - He **looks in the market** : if there is a seller offering a share at the same price  $\implies$  transaction, and the market price at  $t$  is the transaction price. Otherwise,  $P^t = P^{t-1}$

# Simulation process

- ① Initialize a market with  $N$  agents,  $T$  time steps
- ② At each time step  $t$  :
  - All prices are **updated**
  - **One agent** is chosen **randomly** (buyer or seller). Let's suppose it is a buyer
  - He **looks in the market** : if there is a seller offering a share at the same price  $\implies$  transaction, and the market price at  $t$  is the transaction price. Otherwise,  $P^t = P^{t-1}$
  - If there is a transaction, the **buyer becomes a seller**, with a random price in  $\llbracket P^t, P_{\max} \rrbracket$ , and the **seller becomes a buyer**, with a random price in  $\llbracket 0, P^t \rrbracket$

# Physics theory of the diffusion model

Some authors showed that the **position of annihilation** in diffusion models varies with time intervals  $\Delta t$  following :

$$P_{\Delta t} \sim \Delta t^{\frac{1}{4}} \ln(\Delta t)^{\frac{1}{2}}$$

# Physics theory of the diffusion model

Some authors showed that the **position of annihilation** in diffusion models varies with time intervals  $\Delta t$  following :

$$P_{\Delta t} \sim \Delta t^{\frac{1}{4}} \ln(\Delta t)^{\frac{1}{2}}$$

**Analogy** : Diffusion position  $P_{\Delta t} \longleftrightarrow$  Rescaled range  $R_{\Delta t}$

# Physics theory of the diffusion model

Some authors showed that the **position of annihilation** in diffusion models varies with time intervals  $\Delta t$  following :

$$P_{\Delta t} \sim \Delta t^{\frac{1}{4}} \ln(\Delta t)^{\frac{1}{2}}$$

**Analogy** : Diffusion position  $P_{\Delta t} \longleftrightarrow$  Rescaled range  $R_{\Delta t}$

$$R_{\Delta t} \sim \Delta t^{\frac{1}{4}} \ln(\Delta t)^{\frac{1}{2}}$$

# Rescaled range

Figure – The Hurst plot

# Models conclusions

## Stylized fact

- $H > 0.5$  ( $H \approx 0.7$ ) in real markets

## Model's weakness

- "Moving" orders are very **unrealistic**

- 5 Conclusion

# What are we aiming for ?

Our goal is to :

- Introduce a simple mechanistic model of a limit order-driven market

# What are we aiming for ?

Our goal is to :

- Introduce a simple mechanistic model of a limit order-driven market
- Infer qualitative behaviors of the distribution of price fluctuations and long range correlations from simulations

# What are we aiming for ?

Our goal is to :

- Introduce a simple mechanistic model of a limit order-driven market
- Infer qualitative behaviors of the distribution of price fluctuations and long range correlations from simulations

The Maslov model is a theoretical model, which assumes very simple hypothesis upon agents behavior and limit order market structure.

## Quantities of interest

Best ask  $p_a(t)$  and Best bid  $p_b(t)$

The best ask is the lowest price among the ask limit orders

The best bid is the highest price among the bid limit orders

## Quantities of interest

### Best ask $p_a(t)$ and Best bid $p_b(t)$

The best ask is the lowest price among the ask limit orders

The best bid is the highest price among the bid limit orders

### Spread $s(t)$

$$s(t) = \log p(t+1) - \log p(t)$$

## Quantities of interest

Best ask  $p_a(t)$  and Best bid  $p_b(t)$

The best ask is the lowest price among the ask limit orders

The best bid is the highest price among the bid limit orders

Spread  $s(t)$

$$s(t) = \log p(t+1) - \log p(t)$$

Offsetting parameter  $\Delta$

$$\Delta \in \{1, 2, 3, 4\}$$

## Quantities of interest

Best ask  $p_a(t)$  and Best bid  $p_b(t)$

The best ask is the lowest price among the ask limit orders

The best bid is the highest price among the bid limit orders

Spread  $s(t)$

$$s(t) = \log p(t+1) - \log p(t)$$

Offsetting parameter  $\Delta$

$$\Delta \in \{1, 2, 3, 4\}$$

# Hypotheses

Discrete set of time steps

N number of steps during a simulation

# Hypotheses

## Discrete set of time steps

N number of steps during a simulation

## Non finite market

At each step  $t$ , a new agent appears out of a infinite set of agents

# Hypotheses

## Discrete set of time steps

N number of steps during a simulation

## Non finite market

At each step  $t$ , a new agent appears out of a infinite set of agents

## Binary behavior of agents

Two possibilities : make an order at the best price or store a limit order

# Hypotheses

## Discrete set of time steps

N number of steps during a simulation

## Non finite market

At each step  $t$ , a new agent appears out of a infinite set of agents

## Binary behavior of agents

Two possibilities : make an order at the best price or store a limit order

## Unique size for all orders

Unitary lot of stock in each order

# Sequences

- 1 At each step  $t$ , one new agent performs an action

# Sequences

- 1 At each step  $t$ , one new agent performs an action
- 2 Either he is buyer, or he is a seller

# Sequences

- ① At each step  $t$ , one new agent performs an action
- ② Either he is buyer, or he is a seller
- ③ With probability  $q_{lo}$ , he places a limit order, with probability  $1 - q_{lo}$ , he trades at the market price ...

# Sequences

- If a market order is executed, then the corresponding best limit order is removed and its price becomes the new market price

# Sequences

- If a market order is executed, then the corresponding best limit order is removed and its price becomes the new market price
- Else, the price of the new limit order is fixed :  $p = p(t) \pm \Delta$  and a new expiration time is given

# Sequences

- If a market order is executed, then the corresponding best limit order is removed and its price becomes the new market price
- Else, the price of the new limit order is fixed :  $p = p(t) \pm \Delta$  and a new expiration time is given
- For each limit order, if its expiration time is reached, then it disappears from the order book

# Sommaire

  - Simulations and result interpretations
- 5 Conclusion

# Setting Maslov Simulation

Before the evolution of prices, we generate

- an array of bid limit orders  $\{990, 991, \dots, 999\}$
- an array of ask limit orders  $\{1001, 1002, \dots, 1010\}$

At each simulation step  $t$ , two random numbers  $u$  and  $v$  are generated :

- If  $u \leq 0.5$ , the agent is a buyer.
- Else, he is a seller.
- For each :
  - If  $v > q_{lo}$ , the order is an effective market order.
  - The agent places a limit order.

# Setting Maslov Simulation

```
N = 100000
buy_sell_param = 0.5
qlo = 0.5
bids = np.linspace(990,999,10).tolist()
asks = np.linspace(1001,1010,10).tolist()
ask_limit_orders = {i: asks[i] for i in range(10)}
bid_limit_orders = {i: bids[i] for i in range(10)}
initialPrice = 1000
expiration_time = 1000
prices = Maslov_expiration_model(N,buy_sell_param,qlo,bid_limit_orders, ask_limit_orders, initialPrice, expiration_time)
```

Figure – Setting Maslov parameters

We obtain an array of N prices (current price for each step t)

# Market price evolution

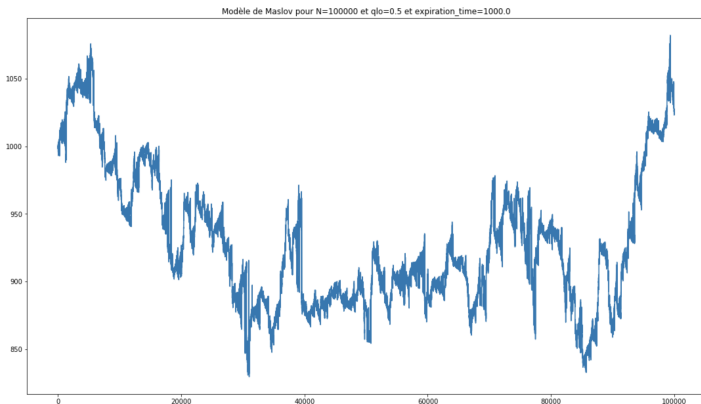

Figure – Evolution of the market price for  $N = 100000$  steps

# Market price increments

Figure – Evolution of the market price increments

# Heavy tails of the log-increments

Figure – The distribution of the log-increments of market prices

# Heavy tails of the log-increments

Figure – The distribution of the log-increments of market prices

# Observations

- High volatility of prices is observed
- Phenomenon of clustering : price increments are grouped and separated by "quiet" zones of fluctuation
- Long-range auto correlation of price
- Shows a non trivial, unexpected Hirst Exponent  $H = 1/4$

  - Study of the 'Mike-Farmer (2008)' model
  - Simulations and result interpretations
- 5 Conclusion

## Quantities of interest

Spread  $s(t)$

$$s(t) = \log p_a(t) - \log p_b(t)$$

## Quantities of interest

Spread  $s(t)$

$$s(t) = \log p_a(t) - \log p_b(t)$$

Logarithmic midprice  $\pi_m(t)$

$$s(t) = \frac{1}{2} (\log p_a(t) + \log p_b(t))$$

## Quantities of interest

Spread  $s(t)$

$$s(t) = \log p_a(t) - \log p_b(t)$$

Logarithmic midprice  $\pi_m(t)$

$$s(t) = \frac{1}{2} (\log p_a(t) + \log p_b(t))$$

Logarithmic returns  $|r(t)|$

$$r(t) = \pi_m(t) - \pi_m(t-1)$$

# Order placement

The model for order placement is developed in the same style as that of Challet and Stinchcombe (2001).

Physics	Challet and Stinchcombe (2001)
Particles	Orders
Infinite lattice	Order book
Deposition	Limit orders submission
Evaporation	Limit orders cancelation
Annihilation	Transaction

**Table –** Analogy between the deposition-evaporation process and the order book of Challet and Stinchcombe (2001)

# Cancellation model

## Introducing an empirical cancellation probability

- The position in the order book  $y(t) = \frac{\Delta(t)}{\Delta(0)}$
- The total number  $N(t) = N_a(t) + N_b(t)$  of orders in the book.
- The order imbalance  $N_{imb}(t) = \frac{N_i(t)}{N(t)}$

$$P(C|y(t), N_{imb}(t), N_t(t)) = A(1 - e^{-y(t)})(N_{imb}(t) + B) \frac{1}{N_t(t)}$$
